

Add a Static Login Page

If you wish to add a custom HTML page for logins, you will need to add a static context inside the Agiloft Setup module. This topic describes the steps to do this.

Prerequisites

- You should already have created the HTML login page and all associated graphics. This topic only describes the steps to configure this page as the default login.
- Stop the EWDatabase and EWServer services in the Task Manager or equivalent before making these changes.
- NGINX must be enabled for your installation. For more information, see [Initial Installation in Linux](#).

Add the Static Login Path

1. Add a Login Page Folder.
 - a. In the installation directory, add a new folder where you will keep the login page files. For example, C:\Agiloft\www\htdocs\logins.
 - b. Add all of the necessary HTML pages, files and graphics.
 - c. If the default login page is index.html, you can login via the directory path. For example in the \logins folder above, you could rename the login-page.html file to index.html. Now the URL to launch your custom login page would look like `http://servername/logins/`.
2. Open the Web Server Settings menu.
 - a. Double click Setup.exe in the installation folder to open the Setup menu.
 - b. Navigate to the main menu then click Web server to open the Web Server Settings.

3. Add a path and a directory.
 - a. In the Web Server Settings menu, the Path refers to the URL relative path and must be prepended with a forward slash - for example, /logins. The Directory refers to the physical path of the folder on the server, for example, C:\Agiloft\www\htdocs\logins.
 - b. Add the Path and Directory based on the login page folder.
 - c. Click the Change web server settings button.

Change web server settings

- d. The application servers will restart with the new static context added.

4. At this point, you will be able to log into the system by navigating to `http://servername/context path/login-page.html` or `http://servername/context path/`.
